Abstract

Background: The liver plays a central role in insulin-like growth factor (IGF) system homeostasis. We examine the protective aerobic training on the IGF system following doxorubicin (DOX) induced hepatotoxicity.

Materials and Methods: In this experimental study 48 Wistar male rats (weighing 257±28 g) were divided into 6 groups: (1) control+placebo (2) control+DOX 10 mg/kg (3) control+DOX 20 mg/kg (4) training+placebo (5) training+DOX 10 mg/kg (6) training+DOX 20 mg/kg. Hepatotoxicity was induced by DOX (10 and 20 mg/kg). Rats in the 4, 5 and 6 groups performed treadmill running of 25 to 54 min/day and 15 to 20 m/min, 5 days/week for 3 weeks.

Results: While, DOX 10 mg/kg administration result in an insignificant increase in IGF-1 and IGF-1/IGFBP-3 and an insignificant decrease in IGFBP-3, DOX 20 mg/kg administration caused a significant increase in IGF-1 and IGF-1/IGFBP-3, an insignificant decrease in IGFBP-3, as compared to the group 1. Three weeks of the endurance exercise resulted in a significant decrease of IGF-1 and IGF-1/IGFBP-3 levels, and significant increase in IGFBP-3, as compared to the group 1. Furthermore, after 3 weeks endurance training and DOX treatment with 10 mg/kg an insignificant decrease in IGF-1, an insignificant increase in IGFBP-3 and a significant decrease in IGF-1/IGFBP-3 were detected, in comparison to group 2.

Conclusion: DOX hepatotoxicity is dose-dependent, acute administration of DOX 20 mg/kg caused an imbalance in the IGF system and protective aerobic training may improve DOX-induced hepatotoxicity by up-regulation of IGFBP3.

Introduction

Over the years, doxorubicin (DOX), as an anti-tumor antibiotics and anticancer [1-6] widely used as a agent in various cancers treatment [7, 8]. Unfortunately, the clinical use of these drugs is limited, because of severe toxic effects of the drug on the body's tissues, including heart, liver, kidneys and nervous system. The mechanisms of DOX-mediated cytotoxicity in cancer cells and normal tissues are different. Cytotoxicity may play a central role in DOX-induced cardiotoxicity or hepatotoxicity [7, 9-12]. In this regard, considerable effort has been in medical and sports field [1-6, 13, 14] to develop strategies to prevent DOX-induced toxicity, especially in heart tissue. Babaei et al. [4] reported the protective effect of morphine on DOX-induced cardiotoxicity. However, few studies have been conducted on the toxicity of DOX in liver tissue. The insulin-like growth factor (IGF) system is an essential regulator of growth and development [15]. In normal conditions, the levels of the components reach a balance, so that the IGF axis plays a critical role in cellular proliferation as well as cell survival [16, 17]. The bioavailability of IGFs is modulated by high-affinity binding proteins known as insulin-like growth factor binding proteins (IGFBPs) (from 1 to 7), that are mainly synthesized in liver. Most of the circulation IGF-1 is carried by IGFBP-3 [15]. IGF system plays a critical role in cell proliferation. Including IGF-1, IGF-2 and family of proteins that binds to IGF (IGFBP), which is specialized bind to IGF [16]. Thus, there is growing evidence to suggest that IGF system is used as a panel of tumor markers for histological diagnosis of various diseases associated with cancer. In this regard, it was reported that insulin-like growth factor (IGF-1) and protein-3 binds to IGF (IGFBP-3) protein-1 binds to IGF (IGFBP-1) are associated with an increased risk of breast cancer in premenopausal women [18]. However, it is not known whether exercise could affect IGF-1 levels and its binding proteins.

Although, there are few longitudinal studies regard the effect of training on IGF-1 proteins, it is not clear whether regular aerobic training could affect the IGF system in the liver tissue. Furthermore, it is not clear that DOX-induced hepatotoxicity by 2 doses of 10 and 20 mg/kg affect of the hepatic IGF system and whether pretreatment with regular aerobic training can affect changes in these parameters? While, many recent studies have focused on the treatment effect of endurance exercise on induce DOX cardiotoxicity [19, 20], the present study was carried out to investigate effect of prior (pretreatment) regular aerobic training against doxorubicin-induced...
hepatotoxicity with various dosages (10 and 20 mg/kg) on insulin-like growth factor (IGF) signaling system (IGF-I, IGFBP-3 and IGF/IGFBP).

Materials and Methods

Experimental Design: The empirically protocols of this experimental study approved by department of physiology, university of Mazandaran and were performed according to guiding procedures in the care and use of animals, prepared by the Council of the American Physiological Society. The experiments were carried out with 48 Wistar male rats (8-week-old, initially weighing 257±28 g), which were obtained from the laboratory of animal bearing and multiplying at the Pasteur institute of Iran. Rats were housed in standard cages of polycarbonate (20×15×15 cm), made at the Pasteur institute of Iran, in a large air-conditioned room with a controlled temperature of 22±2°C, light-dark cycles of 12:12 h and humidity of 50±5%. The pollutant standard index (PSI) was in the acceptable range as determined by the Iranian meteorological organization. Rats were fed with a standard rat chow provided by Pars institute for animals and poultry with a daily regimen of 10 g per 100 g body weight for each rat. Water was available ad libitum.

Familiarization and aerobic training protocols: Animals were habituated to treadmill running for one week (once a day for 10 min/session at 10 m/min, 0% grade). Because rats are more active in darkness, the front portion of the treadmill lines was covered with a dark thick paper to darken this area. At the rear of the lines, an electric grid provided a stimulus for running. An electric stimulus (30 V, 0.5 A) was manually turned on for less than 2 s when the animals stayed on the electric grid for longer than 10 s. Rats quickly learned to stay on the belt and avoid shock, except for one rat, which would not stay on the moving belt, and thus was quickly removed from familiarization process. Following this familiarization period, they were randomly assigned into control and trained groups. Exercise training protocol was performed on treadmill with 0 slopes between 25 to 54 min/session and 15 to 20 m/min, 5 days/week for 3 weeks (Table 1). We replicated the aforesaid exercise training protocol that was previously reported by Dabidi-Roshan et al. [21].

Classification of rats: At the end of the exercise training protocol, rats from the control and trained groups were again randomly separated into subgroups; the DOX (10, 20 mg/kg) and placebo treatment. Thus, the control rats were distributed into control+placebo (group 1, N=8), control+DOX (group 2, N=8) and control+DOX (group 3, N=8) groups and rats in the trained group into trained+placebo (group 4, N=8), trained+DOX (group 5, N=8) and trained+DOX (group 6, N=8) groups.

Doxorubicin treatment: Doxorubicin hydrochloride (EBEWE Pharma Ge.s.m.b.H.Nfg.KG) was dissolved in saline and administered by i.p. injection at 2 dosages of 10 mg/kg [22] and 20 mg/kg [23], and control animals received saline with comparable volume. Both treatments were carried 24 h after the last exercise bout and animals were sacrificed 24 h after DOX and placebo injections.

Liver tissue collection and preparation: Rats in all groups were anesthetized with ketamine and xylazine following 24 h of DOX injection and 12 h fasting. The abdominal cavity was opened to expose the liver tissue. Then liver tissue were rapidly excised, rinsed, carefully dried, weighed and it was placed into Petri dishes containing cold isolation medium (0.1 M/L K2HPO4, 0.15 M/L NaCl, pH=7.4) to remove the blood and were frozen immediately in liquid nitrogen and stored at -80°C. Liver tissue was squashed in liquid nitrogen, homogenized in a lysis buffer (5 mL/g of tissue) with a protease inhibitor cocktail for mammalian cell and tissue extracts (Sigma-Aldrich, St. Louis, U.S.A) 100 ul/1 mL, and 10 mM tris base (Sigma-Aldrich, St. Louis, USA), pH=7.4 and centrifuged at 1500 g for 4°C for 15 min. Hepatic supernatant was diluted 1:30. Plasma was diluted 1:10 homogenized in doubly distilled water. Homogenates were centrifuged (2 min at 2,000 g, 4°C) to eliminate cellular debris, and the resulting supernatant was stored at liquid nitrogen (-80°C) for later determination of insulin-like growth factor (IGF) system include insulin-like growth factor (IGF-I) and insulin-like growth factor binding protein-3 (IGFBP-3).

Quantitative detection of the IGF system: Markers of the IGF system (IGF-I and IGFBP-3) were measured using the following ELISA kits according to the manufacturer’s instructions: IGF-1 ELISA kit (DRG International, USA) and IGFBP-3 Quantikine ELISA Kit (R&D Systems, USA). Absorbance was read at 450 nm for the three kits in a microplate reader. In summary, 100 µL of standard, blank, or sample added per well. The liquid removed of each well and 100 µL of biotin-antibody working solution added to each well. Then, aspirated each well and washed and repeated these step for three times.In addition, 100 µL of HRP-avid in working solution added to each well and the aspiration and washing repeated five times as step 4. Moreover, 90 µL of TMB substrate added to each well. Also, 50 µL of stop solution added to each well when the first 4 wells containing the highest concentration of standards develop obvious blue color. Finally, the optical density of each well was determined within 30 min; a microplate reader set to 450 nm was used.

Statistical Analysis: All data have been expressed as mean±SD. Statistical analysis was performed using a commercial software package (SPSS-20 for Windows). Data of the IGF system were normally distributed after log-transformation. A one-way analysis of variance (Statistics software, Stat Soft, Inc., Tulsa, OK) was used to detect statistical differences between groups. A post-hoc test (Tukey test) was performed to determine differences in the various biomarkers between groups. Differences were considered statistically significant at p-value<0.05.

Result

No difference existed in the age and weight values between rats in the various groups. Changes in IGF-1, IGFBP-3 and IGF-1/IGFBP-3 levels following doxorubicin treatment (DOX 10 mg/kg, DOX 20 mg/kg)
in the various groups showed in figures. Rats in the control group, showed an insignificant increase in IGF-1 and IGF-1/IGFBP-3 (6.8% and 6.41%, respectively), an insignificant decrease in IGFBP-3 (0.04%), following DOX 10 mg/kg administration. However, administration of DOX 20 mg/kg in control group caused a significant increase in IGF-1 ($p=0.05$) and IGF-1/IGFBP-3 ($p=0.01$) (14% and 14.1%, respectively), an insignificant decrease in IGFBP-3 (0.3%) in comparison to rats in the group 1. Also, there was no significant difference between DOX 10 mg/kg and DOX 20 mg/kg treatments in IGF-1, IGFBP-3 and IGF-1/IGFBP-3 levels.

Figures 1, 2 and 3 show changes in IGF-1, IGFBP-3 and IGF-1/IGFBP-3 levels following protective role of 3 weeks of aerobic training in the rats exposed to DOX-induced hepatotoxicity. Three weeks of the regular aerobic training led to an insignificant decrease in IGF-1 ($p=0.02$) and IGF-1/IGFBP-3 ($p=0.01$) (26% and 5.1%, respectively) and a significant increase in IGFBP-3 (96%), as compared to group 1 ($p=0.03$).

Changes in the IGF-1, IGFBP-3 and IGF-1/IGFBP-3 levels, shows in figure 1, 2 and 3. After 3 weeks of aerobic training and DOX treatment with 10 mg/kg, an insignificant decrease in IGF-1 and IGF-1/IGFBP-3 (6.7% and 7.2%, respectively), and an insignificant increase in IGFBP-3 (45%), were detected in comparison to c+DOX 10 group. In addition, protective role of regular aerobic training and DOX treatment with 20 mg/kg resulted in a significant decrease in IGF-1 ($p=0.02$) and IGF-1/IGFBP-3 ($p=0.01$) levels (8.9% and 8.9%, respectively), an insignificant increase in IGFBP-3 (0.29%), as compared to c+DOX 20 group.

Furthermore, after 3 weeks of aerobic training and doxorubicin treatment (10 mg/kg), an insignificant increase in IGF-1 and IGF-1/IGFBP-3 levels (4.01% and 4.05%, respectively), and an insignificant decrease in IGFBP-3 (0.5%), were detected in comparison to group 4. After 3 weeks of aerobic training and doxorubicin treatment (20 mg/kg), an insignificant increase in IGF-1 (8.4%), a significant increase in IGF-1/IGFBP-3 (9.4%) ($p=0.002$) and a significant decrease in IGFBP-3 (9%), were detected in comparison to group 4 ($p=0.05$). However, after 3 weeks of aerobic training and DOX 10 mg/kg and DOX 20 mg/kg treatments there was no significant difference between in IGF-1, IGFBP-3 and IGF-1/IGFBP-3 levels.

Discussion

The present study was designed to determine protective role of regular aerobic training on the IGF system (IGF-1, IGFBP-3 and IGF-1/IGFBP-3) in the rats exposed to DOX-induced hepatotoxicity with the various dosages (10 and 20 mg/kg). The primary novel finding in present study was that, administration of DOX 10 mg/kg and DOX 20 mg/kg led to imbalance in the IGF signaling system in rats. This result indicates potent role of DOX administration in induce oxidative stress. Doxorubicin is an anthracycline antibiotic that is considered as 1 of the most effective antitumor agent. The clinical use of DOX is limited by toxicity to normal tissues, such as the heart and liver [7, 24]. The mechanisms of DOX-mediated cytotoxicity in cancer cells and normal tissues are different [7]. On the other word, DOX-induced cardiotoxicity or hepatotoxicity mainly occurs by generating oxygen free radicals, which is inhibited by free radical scavengers [7]. Oxidative stress plays a major role in DOX-induced cardiomyopathy and hepatic damage. Numerous methods have been used to minimize the cardiotoxic effects of the chemotherapeutic agent doxorubicin, and most have had limited success. Chronic endurance exercise has been shown to protect against DOX hepatotoxicity, but little is known the effects of acute exercise on DOX-induced hepatic dysfunction [25].

There is growing evidence to suggest that the IGF system are used as a panel of tumor markers for histological differentiation [7]. On the other word, DOX-induced cytotoxicity in cancer cells and normal tissues are different [7]. The resting IGF-1/IGFBP-3 ratio was significantly higher in athletes. These results indicate that elevation of baseline serum IGF-1/IGFBP-3 ratio after exercise might suggest that free fractions of these hormones may act as a potent stimulant of muscle hypertrophy in trained endurance athletes. Graded exercise tests had a significant effect on serum IGF-1 concentration at maximal intensity of exercise.

Furthermore, at maximal exercise, higher values of serum IGF-1, IGFBP-3, and IGF-1/IGFBP-3 ratio were found in athletes compared to control group [30]. Sprod et al. [31] found an inverse relationship between changes in IGF-1 and changes in overall health related quality of life, physical role limitations, and social functioning. Changes in IGFBP-1 and IGFBP-3, binding proteins for IGF-1, were correlated with changes in physical role limitations and physical functioning, respectively.

Early epidemiological evidence does not support an inverse association between chronic exercise and circulating levels of IGF1 and IGFBP3, particularly in older women. A recent review also suggested that long term exercise may actually increase circulating IGF1. Therefore, the evidence is weak that chronic exercise lowers IGF-1 levels [32].

In conclusion, the present findings demonstrate that the hepatotoxicity induced by DOX 20 mg/kg, may be related to imbalance of IGF system in liver tissue. Moreover, protective role of 3 weeks aerobic training effectively improve the toxic effects of DOX in liver, it was suggested that free fractions of these hormones may act as a potent stimulant of muscle hypertrophy in trained endurance athletes. Graded exercise tests had a significant effect on serum IGF-1 concentration at maximal intensity of exercise.

Moreover, protective role of 3 weeks aerobic training effectively improve the toxic effects of DOX in liver, so that it was associated with up-regulation of IGFBP-3 and down-regulation of IGF-1. Overall, our study suggests that short-term regular aerobic training before administration of DOX may be considered as a potentially useful strategy to limit hepatotoxicity before DOX therapy and improve IGF system in liver tissue.
