Abstract

Background: Health Transformation Plan (HTP) has been one of the biggest reforms in Iran's health system over the past 3 decades. The plan has been implemented since May 2014 and includes several packages that can affect the utilization of health care services. We aimed to assess the effect of implementation of HTP on utilization of specialist outpatient visit rate in clinics affiliated to university hospitals.

Methods: We chose Kurdistan province to collect monthly specialist outpatient visit data for 50 months because this province was not a patient referral hub. An interrupted time series (ITS) analysis and segmented regression analysis were used to evaluate the effects of HTP on specialist outpatient visit rates. Statistical analyses were conducted using STATA version 13.

Results: A significant increase was observed in the specialist outpatient visit rate (12.1 outpatient visit per 1000 population) in the first month after the implementation of HTP ($p=0.000$, 95% CI= 6.36-17.83). Also, after the implementation of HTP, a significant increase was observed in the monthly trend of specialist outpatient visit rate equivalent to about 0.53 every month per 1000 population compared to the monthly trend in specialist outpatient visit rate before the intervention ($p=0.033$, 95% CI= 0.04-1.01).

Conclusion: HTP has significantly increased the specialist outpatient visit rate in clinics affiliated to university hospitals in Kurdistan province. Thus, it is necessary to perform some comprehensive studies on all public, private, and semi-private sectors in different parts of the country to provide a better and more comprehensive picture of the effects of HTP on utilization of specialist outpatient visit services.

Introduction

The main point behind health services utilization is to create access to health services for those who are in need (1, 2). Receiving and using health services is called health care utilization, and access to health services is the concept of opportunity and ability to use services. This definition is a reflection of the theory that there should be a set of conditions through which a person who is in need of health services can use those services (3, 4).

Financial, geographic (physical and time distance to service provider), cultural (acceptability), and availability (service delivery, waiting time, availability of qualified providers, right technology) constitute the 4 main dimensions of access. Access to health services has a positive impact on health services utilization. Thus, health system policy-makers should try to improve these dimensions to increase the services utilization. Since health utilization is

↑What is “already known” in this topic:

In Iran, no study has ever been done to assess the effect of implementation of HTP on utilization of specialist outpatient visit services.

→What this article adds:

The implementation of HTP has significantly increased the utilization of specialist outpatient visit services in university hospitals.

a complex issue and influenced by several factors, a structural change may lead to a sudden change in utilization behavior (5-7).

Universal health coverage (UHC) is an important step towards utilization of health services. UHC has 3 dimensions: covered costs, covered services, and covered individuals. However, the desired quality of health services can be considered as the fourth aspect (8). The ultimate goal of UHC is to benefit everyone from essential health services without enduring financial risk or becoming poor because of health care expenditures (8-10).

There has been a rising interest in moving towards universal health coverage in the recent years. Most of the countries that have achieved UHC are high-income countries and a member of Organization for Economic Cooperation and Development (OECD). However, some low-income countries, such as Chile, Brazil, Thailand, Mexico, and Turkey, have also moved towards UHC (11-16). Iran has also been working to achieve UHC over the past 2 decades, but reaching this goal has been postponed because of some challenges: low contribution and instability of health system resources due to economic crises, lack of a transparent and efficient tax system, and the impact of fluctuations on oil prices. However, the only determining factor to achieve UHC is not the economic conditions of countries (17).

Iran's health system has started a series of reforms called "Health Transformation Plan" since May 2014. HTP focuses on 3 approaches: provision of access to health services, financial protection of people, and promotion of quality of services. So far, various packages have been implemented based on these 3 phases (18). Some of these packages, which can- directly or indirectly- affect the utilization of outpatient and inpatient health services, are as follow:

- Insuring Iranians with no basic health insurance for free
- Encouraging and supporting the retention of physicians in deprived areas to increase people's access to health care services in the second and third levels by offering incentive payments to the physicians depending on the extent of underdevelopment of the region
 - A 24-hour presence of resident specialist physicians in university hospitals to provide timely utilization of health care services
 - Improving the quality of visiting services in university hospitals through increasing the motivation of physicians and keeping them in public sector, increasing their willingness to work in hospitals' specialist clinics, maintaining and increasing the number of full-time faculty members in university hospitals, standardizing visit times, and improving the quality of outpatient care services

After implementing this package, medical tariffs for full-time physicians working in outpatient clinics of hospitals are calculated twice the amount of the public sector tariffs taking into account the standards of visit time, creating an outpatient medical record, and keeping accurate records of patient's medical history and measures taken for the patients. To avoid any increase in out-of-pocket payment for patients, this incentive tariff is paid by basic

insurance organization. However, this does not include physicians who work in private sectors.

▪ Also, due to implementation of the first phase of HTP, private activity for physicians in service (K coefficient physicians) is prohibited and these physicians must be hired full-time by university hospitals. Moreover, incentive tariffs are considered to increase the incentive of these physicians and other physicians (faculty and non-faculty members) who are hired full-time by university and do not work in private sector. This incentive tariff is paid by a basic insurance organization to prevent a rise in out-of-pocket payments for patients (19).

Measures taken in the framework of HTP, especially those undertaken during the first phase, can affect the dimensions of access to health services and subsequently the utilization of health services. This study seeks to answer the following question:

How the implementation of HTP has affected the specialist outpatient visit rate in university hospitals?

Methods

In this study, interrupted time series was used to investigate the short-term (in the first month) and long-term effects of the HTP (intervention) on specialist outpatient visit rate. In interrupted time series, measurements are made periodically from the dependent variable before and after the intervention. Interrupted time series design does not require the control group to create causal relationship between the intervention and the outcome. It is the strongest type of quasi-experimental studies to assess the short-term and long-term effects of one or more interventions (20, 21).

We assumed that the interventions of HTP have more effects on utilization of health care services in provinces where the economic level of the household is weaker. We also needed to choose provinces that would not be the referral hub for other provinces; and Kurdistan province had these criteria. This province is located in west of Iran with the population of 1 603 011 (22). The studied community included all patients who used specialist outpatient visits in hospitals affiliated to Kurdistan University of Medical Sciences from March 21, 2012 to May 21, 2016. This province has 11 university hospitals.

In this study, outpatient visit services include specialist visits provided to outpatients in the clinics of hospitals affiliated to Kurdistan University of Medical Sciences under the title of "Specialist Clinic". These clinics include infectious disease, neuropsychology, ophthalmology, anesthesia, neurology, dermatology, orthopedics, internal, oncology, lung, surgery, cardiology, obstetrics and gynecology, ENT, nephrology, and nutrition clinics. In this study, the sample size consisted of 50 monthly observations (25 observations before implementation of HTP and 24 after the initiation of HTP). HTP was already implemented for observation No. 26. The data for this study were obtained from the center of statistics of the studied hospitals. To eliminate the impact of population growth on utilization of services, the frequency of outpatient service utilization was divided by the population under study.

In addition, a segmented regression analysis was used to

analyze the time series data. The segmented regression fits the regression model by ordinary least squares (OLS). We used the Newey–West approach in our estimation. This model estimates the coefficients of OLS regression and produces Newey–West standard errors to handle autocorrelation and possible heteroskedasticity (18, 24).

In time series, changes in the dependent variable of the intervention are divided into 2 general categories: changes in level and changes in slope. A change in the level indicates a quick or short-term change (in the first month after the intervention) and the change in slope (monthly trend) represents a long-term change in the dependent variable (23, 24).

The regression model used to estimate the effect of HTP on outpatient visit services utilization in specialized clinics of Kurdistan University of Medical Sciences is as follows (Equation 1):

$$Y_t = \beta_0 + \beta_1 \text{time}_t + \beta_2 \text{intervention}_t + \beta_3 \text{time after intervention}_t + \epsilon_t$$

where Y_t is outpatient visit rate in month t ; time_t represents time in months at time t from the start of the observation period; intervention_t is a dummy (indicator) variable representing the intervention (pre-HTP period is 0, otherwise is 1), which was implemented at month 26 in the series, and $\text{time after intervention}_t$ is counting the number of months after the implementation of HTP at time t ; β_0 represents the intercept or starting level of the outpatient visit rate; and β_1 is the slope of outpatient visit rate until the implementation of HTP. β_2 represents the changes in the level of outpatient visit rate in the period immediately following the implementation of HTP (compared to the counterfactual); and β_3 represents the difference between

pre- and post-HTP slopes of outpatient visit rate.

In this study, stationarity of residuals was tested using Dickey- Fuller test and it showed that the residuals were stationary ($p= 0.049$). The Newey with one lag was also used to estimate the coefficients of the model. To ensure that we estimated a model that accounted for the correct autocorrelation, we used the actest with lags (12). Autocorrelation was seen just at lag 1 but not at any higher lag orders. Thus, the initial model correctly accounted for this autocorrelation (24). Also, residuals normality was tested and found to have a normal distribution (20-18). All data were analyzed using STATA version 13.

Results

Regression results are presented in Table 1. In the beginning of the study, the average rate of monthly specialist outpatient visit was 17.94 per 1000 population. The specialist outpatient visit rate had increased by 0.16 every month per 1000 population before. However, the increase in specialist outpatient visit rate was not statistically significant ($p= 0.160$, 95% CI= 0.066-0.391). Nonetheless, in the first month after the implementation of HTP (short effect), there was a significant increase in the specialist outpatient visit rate (12.096 visit rate per 1000 population, $p< 0.001$). Also, the difference in the monthly trend of specialist outpatient visit rate was significant before and after the intervention ($p= 0.033$). After the implementation of HTP, a significant increase, equivalent to about 0.53 every month per 1000 population, was seen in the specialist outpatient visit rate (compared to the monthly trend of specialist outpatient visit rate before the intervention) in university hospitals (Table 1).

The visual display for specialist outpatient visit rate per 1000 population before and after HTP in university hospitals in Kurdistan province is as follows (Fig. 1).

Discussion

Our findings showed that implementation of HTP resulted in a statistically significant increase in specialist outpatient visit rate in hospitals affiliated to Kurdistan University of Medical Sciences. The specialist outpatient visit rate increased by 12.096 visits per 1000 population in the first month after HTP. Also, monthly trend of specialist outpatient visit rate increased by 0.591 per 1000 population compared to the period before implementation of HTP. Increase in the specialist outpatient visit rate can be attributed to a reduction in the cost of outpatient visits in the university hospitals, providing free basic health insurance for people without insurance, longer retention of specialist physicians in the university hospitals, increased patient satisfaction, changing hospitals' behavior and willingness to work in university outpatient clinics after the implementation of HTP. Also, after implementation of HTP, some of the physicians, especially those working in deprived regions, could work only in university hospitals and they could not work in private sectors. This could have shifted outpatients from private sectors to outpatient university clinics. In Iran, about 17% of the population had not been covered by any health insurance in 2010. However, after implementation of HTP, nearly 11 million people without health insurance were covered by Iran Health Insurance Organization by August 2016. This number was about 360 000 for Kurdistan province (25). The positive relationship between health insurance and the possibility of using outpatient services has been confirmed in studies conducted in Iran (2, 26-28). Consistent with our results, the number of specialist outpatient visits in specialist clinics in Khorasan Razavi province increased by 30% after about 8 months of implementing HTP compared to before HTP implementation (29). A national study was conducted in Kermanshah province to examine the effect of HTP on hospitalization rate. The results indicated that implementation of HTP had significantly increased hospitalization rate in university hospitals and that the decrease in OOP payment could be the reason for this increase. Theoretically, health insurance can have an impact on the use of health services in 2 ways. First, insurance may reduce the cost of health care at the time of purchase, which may lead to more access and use of health services by people. Part of this increase in consumption may be unnecessary and due to the consumer moral hazard. The consumer moral hazard occurs when the insured people request more health services than the uninsured, as the cost of receiving the service is less than the actual cost of the service. Secondly, health insurance may increase the use of health services due to the provider-induced demand (provider moral hazard) (30-33). In general, the money paid by patients influences the volume of services used by them and the volume of services provided by health service providers (31). Some services, such as physician's request for a visit, are highly elastic and having an insurance coverage can increase their use. From the view-

point of health policy-makers, one of the main concerns about HTP is provider-consumer moral hazard (34). Therefore, the increase in the specialist outpatient visits rate may be divided into 2 parts. One includes meeting unfulfilled real needs that previously existed due to lack of access to these services (pre-existing unmet need) that are now fulfilled because of implementation of HTP; and the other includes unnecessary services due to provider-consumer moral hazard. The findings of Rand study showed that the price elasticity for outpatient services is higher than inpatient services (35). The study of Wagaste et al in China confirmed the positive impact of health insurance on using outpatient services (36). Also, Trujillo et al in Columbia revealed that health insurance has had a positive impact on using health services by poor people and those without insurance coverage (37). Also, the initial results of Thai Health Reform Program, known as 30-Baht UHC, showed that insurance has increased the access to outpatient health services (38).

Limitations

This study was conducted only in university hospitals in Kurdistan province, western Iran. Thus, its results cannot be generalized to all provinces of the country. Also, this study investigated the effect of HTP on outpatient visit rate 2 years after HTP implementation, as HTP had been implemented for 2 years at the time of conducting this study. Therefore, it is recommended to consider longer time periods for future studies.

Conclusion

We found a statistically significant increase in the specialist outpatient visit rate in the first month and monthly trend after HTP implementation in specialist clinics affiliated to Kurdistan University of Medical Sciences. However, it is essential to conduct comprehensive studies on all public, private, and semi-private sectors in different parts of the country to provide a more comprehensive picture of the effects of HTP on utilization of specialist outpatient visit services.
